# Plan

## I. R Basics

- A. What is R
- B. Ressources
- C. Basic knowledge (variable type, classic functions)

## II. R objects for NGS

- A. Data bases
- B. Genomic object
- C. Specific tools

## III. R plots

# R Basics

# What is R?

- ❑ A calculator

```
## All mathematical / statistical functions implemented in the basics  
 $(5+5)*10^4$   
sqrt(16) / factorial(50)
```

- ❑ A programming language

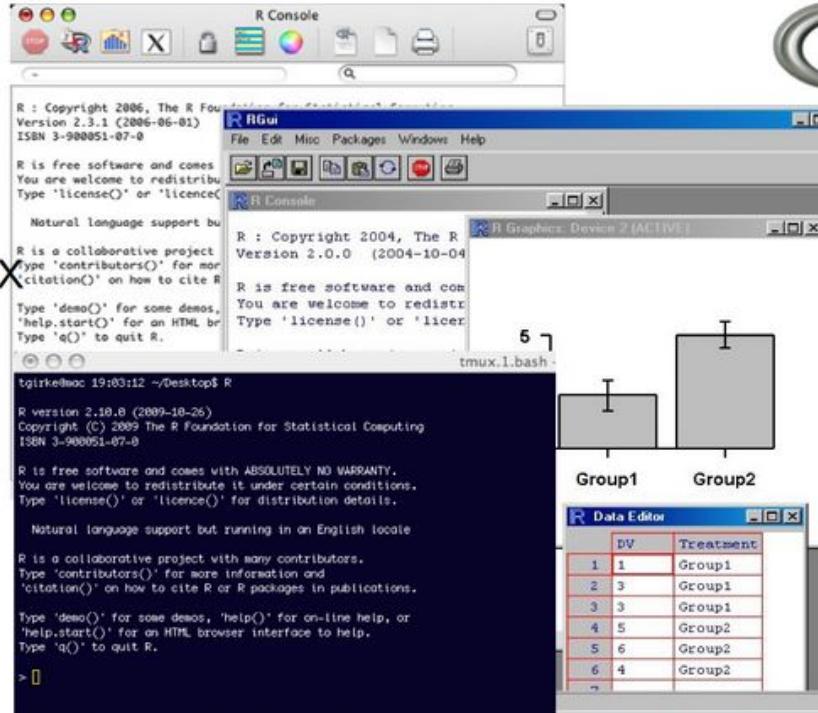

```
## Automatisation of repetitive tasks / functions  
  
for (i in 1:50){  
  print(i^2)  
}
```

```
hello.world <- function(){  
  print("Hello World")  
}
```

- ❑ An open source software
- ❑ A very active community that have already provided > 4000 extensions.

# How to play with R? Console

The screenshot shows the Bioconductor website's "About" page. At the top, there is a navigation bar with links for Home, Install, Help, Developers, and About. A search bar is also present. The main content area has a breadcrumb trail "Home » About". It describes Bioconductor as an open source project for genomic data analysis using R. It mentions the release version (twice yearly), development version (prior to incorporation), and meta-data packages. Citations for the project are provided, along with sections on Bioconductor Packages and Project Goals.

Home » About

Bioconductor is an open source, open development software project to provide tools for the analysis and comprehension of high-throughput genomic data. It is based primarily on the [R](#) programming language.

The Bioconductor [release version](#) is updated twice each year, and is appropriate for most users. There is also a [development version](#), to which new features and packages are added prior to incorporation in the release. A large number of [meta-data packages](#) provide pathway, organism, microarray and other annotations.

The Bioconductor project started in 2001 and is overseen by a [core team](#), based primarily at [Roswell Park Cancer Institute](#), and by other members coming from US and international institutions.

Key citations to the project include Huber et al., 2015 [Nature Methods 12:115-121](#) and Gentleman et al., 2004 [Genome Biology 5:R80](#).

### Bioconductor Packages

Most Bioconductor components are distributed as [R packages](#). The functional scope of [Bioconductor packages](#) includes the analysis of DNA microarray, sequence, flow, SNP, and other data.

### Project Goals

The broad goals of the Bioconductor project are:

- To provide widespread access to a broad range of powerful statistical and graphical methods for the analysis of genomic data.
- To facilitate the inclusion of biological metadata in the analysis of genomic data, e.g. literature data from PubMed, annotation data from Entrez genes.
- To provide a common software platform that enables the rapid development and deployment of extensible, scalable, and interoperable software.
- To further scientific understanding by producing high-quality [documentation](#) and reproducible research.
- To [train](#) researchers on computational and statistical methods for the analysis of genomic data.

# Which type of variable?

## No dimension

- ❑ Numeric (float)

```
x <- c(3,2,0,5);y <- "85"  
is.numeric(x); as.numeric(y)
```

- ❑ Integer

```
is.integer(x); as.integer(x)
```

- ❑ Character / String

```
as.character(x); nchar("Boo")  
paste("Boo", "Boo")
```

- ❑ Logical (T/F)

```
3 %in% x; !(x < 3); TRUE==T  
which(x < 3); T+TRUE+F+FALSE
```

## Undefined values

- ❑ Non existing number

```
## NaN, Inf  
x / 0
```

- ❑ Null data (NULL)

```
z <- NULL; length(z); is.null(z)  
z + 2
```

- ❑ Missing data (NA)

```
x <- c(3,2,0,5,NA); class(x)  
is.na(x); na.omit(x)  
mean(x); mean(x,na.rm=T)
```

# Combine elements: Constraint on type

## ❑ Vector (1D)

```
x <- c(3,2,0,5)
y <- c("85",8,9)
x[2]
seq(1,6,1)
rep(y,3); 1:6; x[2:3]
x^2; x + x[2:3]
```

## ❑ matrix (2D) / Arrays (ND)

```
# 2 dimensions
x2 <- matrix(1:12,nrow=4,ncol=3,byrow=TRUE)
x2[3,2]; x2[,2]
x2 + x2
x2 + c(3,2,5)
x2[,1] <- c(3,2,5)
dim(x2); row.names(x2)
# 3 dimensions
x3 <- array(1:12,dim=c(2,2,3))
x3[1,2,2] ; x3[1,2,]
```

## ❑ Factor: categorical vector(1D)

```
# limited number of different values, encoded
in integer, used by read.table()
data <- factor(c(3,2,0,5,3,2,0,5,3,2,0,5))
as.integer(data)
data==5; data=="5"
sum(data)
levels(data) <- c("bleu", "jaune", "rouge", "gris")
```

## ❑ In a general manner, to access the data:

```
x[indexes.dim1]
x2[indexes.dim1,indexes.dim2]
x3[indexes.dim1,indexes.dim2,indexes.dim3]
xN[indexes.dim1,indexes.dim2,indexes.dim3,...,indexes.NDim]
```

# Combine elements: Not constraint on type

## ❑ data frame (2D)

```
# collection of vectors and/or factors  
# constrained by column  
firstNames <- c("Remy", "Lol", "Pierre", "Domi", "Ben")  
IMC <- data.frame(sex=c("H", "F", "H", "F", "H") ,  
                   height=c(1.83,1.76,1.82,1.60,1.90),  
                   weight=c(67,58,66,48,75),  
                   row.names=firstNames)
```

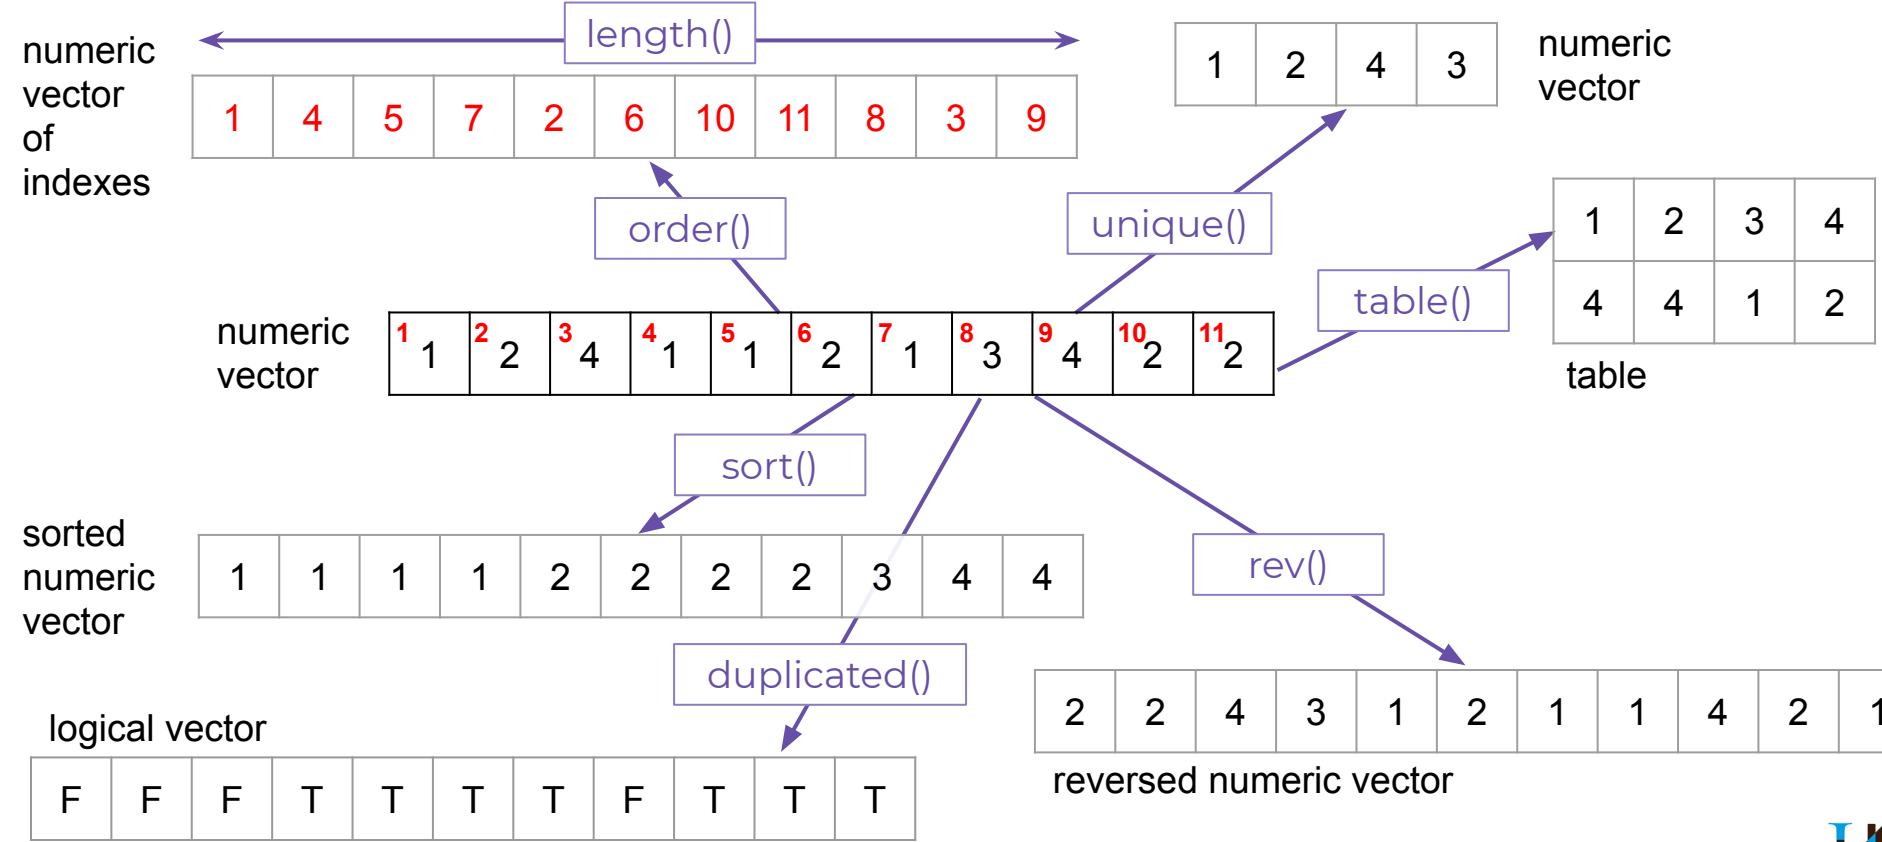

```
IMC$height  
IMC[, "sex"]  
IMC["Remy",]  
IMC[3,2]  
head(IMC)  
colnames(IMC)
```

## ❑ list

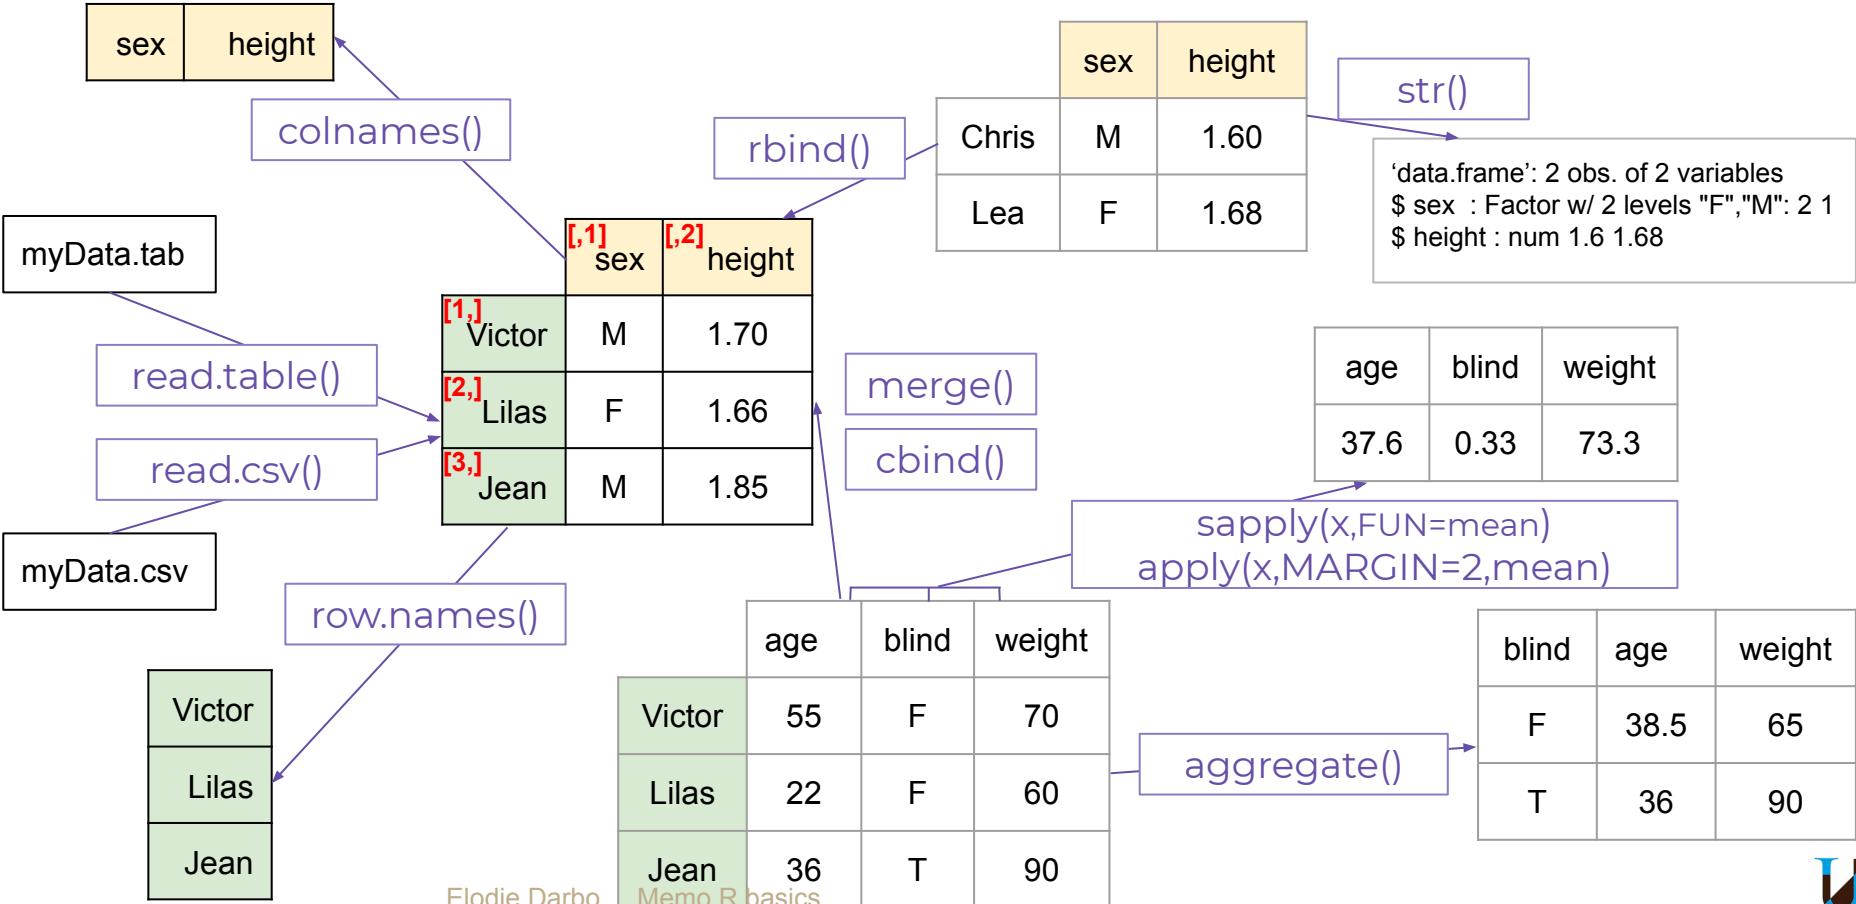

```
# very flexible, store everything  
list.ex <- list(one_vec=1:12,  
                 one_name="Boo",  
                 one_tab=matrix(1:4,nrow=2))
```

```
list.ex$one_tab  
list.ex[[1]]  
list.ex$new <- list(a="a",b="b")  
list.ex$new$a
```

# Manipulate vectors

# Manipulate data frames

# How would you?

```
load("TP_RNAseq/R_course_objects.RData")
# We will use the data.frame objects imc and imc_age
```

- Assemble the 2 data frames?
  - What do they have in common?
- Get the mean weight per gender?
- Get the mean values for all numeric information?

# How would you? ... Answer

```
load("TP_RNAseq/R_course_objects.RData")
# We will use the data.frame objects imc and imc_age
```

- Assemble the 2 data frames?
  - What do they have in common?
- Get the mean weight per gender?
- Get the mean values for all numeric information?

```
# merge the data frames
imc_merged=merge(imc, imc_age, by=c( "prenom", "sexe"))
# Aggregate
aggregate(poids~sexe,imc_merged,mean)
# get numeric columns
numCol <- sapply(imc_merged,is.numeric) # returns logical
imc_num <- imc_merged[,numCol]
# apply on columns the function mean
apply(imc_num,2,mean)
sapply(imc_merged[,numCol],mean)
```

# R Objects for NGS

# Why using R for NGS analysis?

To replace existing command-line tools?

- R NGS treatment built on existing tools (BWA, BowTie, Samtools ...) and data bases (EnsEMBL ...)

To have a analysis workflow?

- No magic ready-to-use solution, constant evolving tools, constant new, more performant methods. Package documentation **must** be consulted !

To take advantage of statistical methods?

To manipulate large data (consulting, filtering, modifying)?

- Import/export of NGS format files (BAM, vcf etc) in specific R objects

To visualise graphically data and results?

# NGS oriented packages & functions

## nucleic/protein sequences (FASTA)

GC content, pattern matching

**Biostring**: e.g. `getSeq()`, `vcoutPattern()`

## reads (FASTQ)

Quality control, cleaning

**ShortRead**: e.g. `FastqSampler()`,  
`readFastq()`, `qa()`, `report()`, `sread()`

## alignment (BAM/SAM)

Manipulate, storage

**GenomicAlignment**: e.g. `filterBam()`,  
`readAlignment()`, `scanBam()`

## SNPs (VCF)

Predict protein impact, prioritize mutations (drivers)

**VariantAnnotation** e.g. `readVcf()`, `rowRanges()`,  
`predictCoding()`

## regions (GFF/BED)

Genomic interval overlap, storage

**GenomicRanges** e.g. `findOverlaps()`,  
`intersect()`, `reduce()`

## metadata (GFF/BED/WIG/ucsc tracks)

Annotations with informations on the  
biological objects (gene, genomic  
region)

**BiomaRt** e.g. `getBM()`

**rtracklayer** e.g. `import()`, `export()`

**GenomicFeatures** e.g. `makeTxDB()`

## all-in-one (from FASTQ to specific results)

Build a workflow with no problem of  
compatibility

**QuasR** e.g. `qa()`, `qAlign()`, `qCount()`

**Rsubread** e.g. `buildIndex()`, `align()`,  
`featureCounts()`, `extractSNP()`

# GenomicFeatures: Extract informations from TxDB objects

# How would you?

```
library(org.Hs.eg.db)  
library(TxDb.Hsapiens.UCSC.hg19.knownGene)
```

- Get CDS from BRCA1 (key type is SYMBOL) in human genome hg19?
  - Does it exist in both OrgDB and TxDB objects?
  - Knowing ENTREZID from OrgDB correspond to GENEID in TxDB, how to get CDS list by transcripts?

# How would you? ... Answers

```
library(org.Hs.eg.db)
library(TxDb.Hsapiens.UCSC.hg19.knownGene)
```

- Get CDS from BRCA1 (key type is SYMBOL) in human genome hg19?
  - Does it exist in both OrgDB and TxDB objects?
  - Knowing ENTREZID from OrgDB correspond to GENEID in TxDB, how to get CDS list by transcripts?

```
# The SYMBOLs are not present in the TxDB, from OrgDB find the corresponding ENTREZID. The key is the gene symbol, the required information in the ENTREZID.
```

```
eid=select(org.Hs.eg.db, "BRCA1", "ENTREZID", "SYMBOL")[[["ENTREZID"]]]
```

```
# Now you can get the transcript names (TXNAME) from the GENEID in TxDB
```

```
txid <- select(x=TxDb.Hsapiens.UCSC.hg19.knownGene, eid, "TXNAME", "GENEID")$TXNAME
```

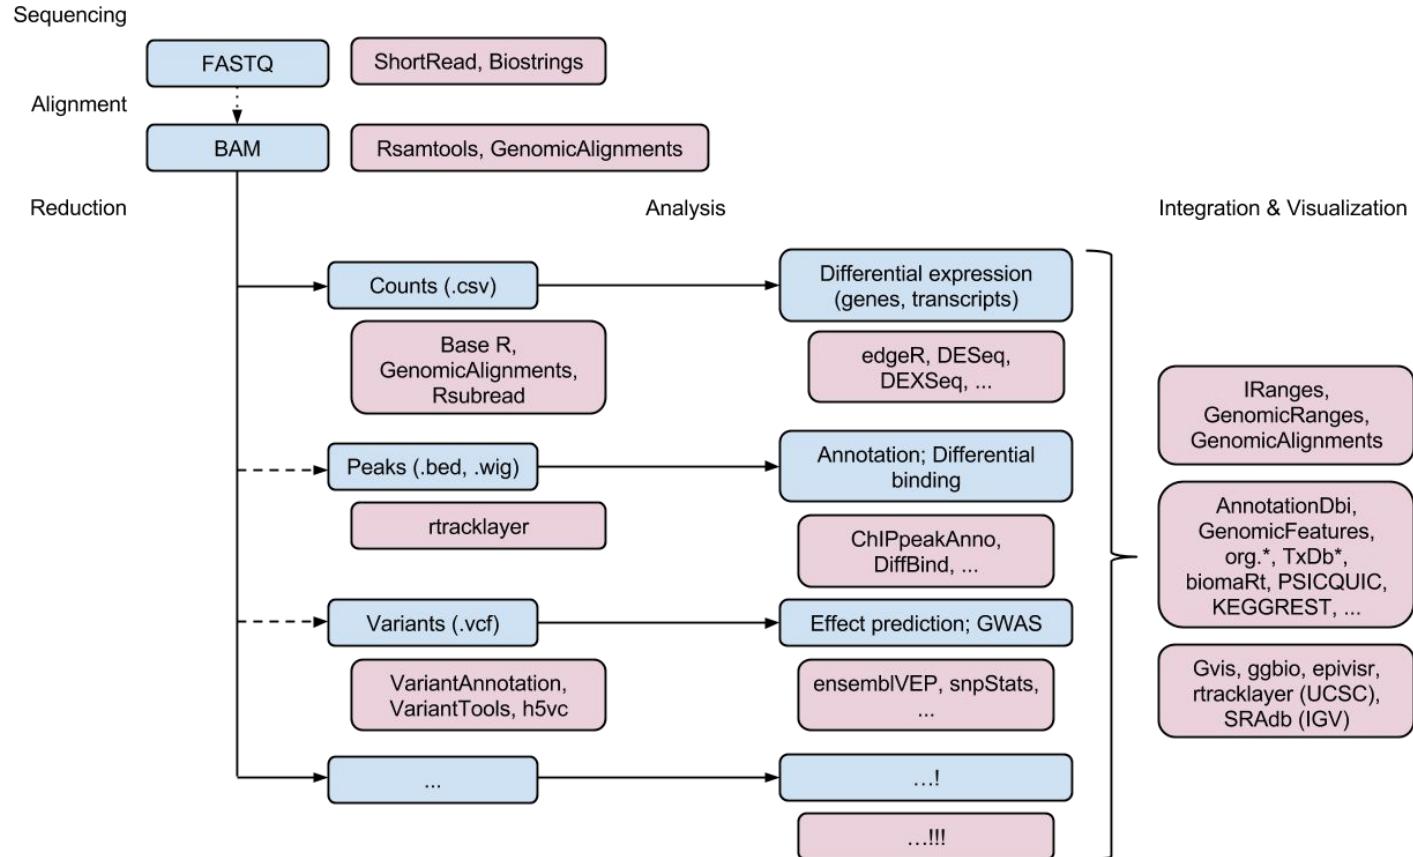

```
# Extraction of CDS by transcripts specifying its transcript names
```

```
cds <- cdsBy(TxDb.Hsapiens.UCSC.hg19.knownGene, by="tx", use.names=TRUE)
```

```
# Select in the cds object (GRanges) the cds relative to the BRCA1 transcripts
```

```
brca1cds <- cds[names(cds) %in% txid]

Version: 2015-01-07  
URL: <https://CRAN.R-project.org/view=Graphics>

R is rich with facilities for creating and developing interesting graphics. Base R contains functionality for many plot types including : as device drivers for all platforms running R, [lattice](#) and grid are supplied with R's recommended packages and are included in every graphics environment than the base R graphics.

R's base graphics are implemented in the same way as in the S3 system developed by Becker, Chambers, and Wilks. There is a static global parameters such as margins and layouts which can be manipulated by the user using `par()` commands. The R graphics engine redrawing a whole plot. This situation may change in R 2.7.x, where developers are working on double buffering for R devices. Even

One can quickly run into trouble with R's base graphic system if one wants to design complex layouts where scaling is maintained or limitations and as a result packages like [lattice](#), [ggplot2](#), [grid](#) or [hexbin](#) use grid for the underlying primitives. When using plots grid commands, e.g., `grid.polygon()` rather than `polygon()`. Also grid maintains a stack of viewports from the device and one needs vignettes.

The graphics packages in R can be organized roughly into the following topics, which range from the more user oriented at the top to

- Plotting :** Enhancements for specialized plots can be found in [plotrix](#), for polar plotting, [vcd](#) for categorical data, [hexbin](#) for hexagonal binning, which also has an implementation of Tukey's bag plot. For 3D plots [lattice](#), [scatterplot3d](#) and [mice](#) or [rgl](#). The package [onion](#) for visualizing quantiles and octonions is well suited to display 3D graphics based on derived metrics.
- Graphical Applications :** This is not much different from the plotting section except that these packages have tools that may subject areas, like medical imaging, the relevant task view contributed by other dedicated userR's is an excellent place to start.
- Effect ordering :** The [grid](#) package focuses on the ordering of graphs to accentuate cluster structure or natural ordering t criteria. For ordering an array of displays, [grid.layout](#) can be useful.
- Large Data Sets :** Large data sets pose very different challenges from moderate and small datasets. Aside from very quickly, and [hexbin](#) can bin bivariate data onto a hexagonal lattice, the advantage being that the irregular lines and t with [lattice](#). An alternative is to use [seaglass](#) to produce a scatterplot matrix of "data about the data", and look for interesting patterns.
- Trees and Graphs :** [ape](#) and [ade4](#) have functions for plotting phylogenetic trees, which can be used for plotting dendrogram placement, so may be useful for very large trees. [igraph](#) has the Tifford-Rheingold algorithm implemented and is use [igraph](#) have functions for plotting and layout, especially useful for representing large networks.
- Graphics Systems :** [lattice](#) is built on top of the grid graphics system and is an R implementation of William Cleveland's trellis implementation of the system described in "A Grammar of Graphics" by Leland Wilkinson. Like [lattice](#), [ggplot2](#) (also built on more emphasis on reshaping data, transformation, and assembling the elements of a plot...).
- Devices :** Whereas grid is built on top of the R graphics engine, many in the R community have found the R graphics engine sc basic supplies devices for PostScript, PDF, JPEG and other formats. Devices on CRAN include [cairoDevice](#) which is a device t the Gimp Tool Kit, similar to pyGTK2. [RSvgDevice](#) is an SVG device driver and interfaces well with vector drawing program standard. Trust Microsoft, [rgl](#) provides a device driver based on OpenGL, and is good for 3D and interactive development. Las
- Colors :** The package [colorspace](#) provides a set of functions for transforming between color spaces and [mixcolor\(\)](#) for mixing suitable for coding categorical variables (`rainbow`, `heat.colors`) and numerical information (`sequential_hcl()`, `diverge_hcl()`).
- Interactive Graphics :** There are several efforts to implement interactive graphics systems that interface well with R. In the case of edge as well as link with other views of the data, [rgobi](#) embeds the GGobi interactive graphics system within R, so that t GGobi's edge set functionality. The RoSuDA repository maintained and developed by the University of Augsburg group has two graphics tools contain functions for alpha blending, which produces darker shading around areas with more data. This is except versions of R graphics using the [cairoDevice](#) and [RGtk2](#). Lastly, the [rgl](#) package has mechanisms for interactive manipulation.
- Development :** For development of specialized graphics packages in R, grid should probably be the first consideration for any Java device in the RoSuDA packages, though Java has its own drawbacks. For porting plotting code to grid, using the pack

CRAN packages:

- [ade4](#)
- [animation](#)
- [ape](#)
- [grid](#)

## R graph gallery

The blog is a collection of script examples with example data and output plots. R produce excellent quality graphs for research, science and business presentation, publications and other purposes. Self-help codes and examples are provided. Enjoy nice graphs !!

The screenshot shows the homepage of the R graph gallery. At the top, there is a large logo with the letters 'R' in a stylized font. Below the logo, the text 'Graph Gallery: A collection' is displayed. The main content area features several small thumbnail images of R plots, each with a caption below it. To the left of the thumbnails, there is a column of text containing R code snippets. The code snippets are related to various plotting functions in R, such as 'barplot', 'hexbin', 'heatmap', 'histogram', 'kerneldensity', 'lattice', 'lxy', 'points', 'stackedbar', 'treemap', and 'xypoints'. The R code is presented in a monospaced font. The overall layout is clean and organized, making it easy to browse through the different types of plots and their corresponding source code.

# Some useful R packages

CRAN Task View: Graphic Displays & Dynamics

Maintainer: Nicholas Lewin-Koh  
Contact: nikko@hailmail.net  
Version: 2015-01-07  
URL: <https://CRAN.R-project.org/view=Graphics>

R is rich with facilities for creating and developing interest as device drivers for all platforms running R, [lattice](#) and graphics environment than the base R graphics.

R's base graphics are implemented in the same way as in the global parameters such as margins and layouts which can't redraw a whole plot. This situation may change in R 2.4.

One can quickly run into trouble with R's base graphic system limitations and as a result packages like [lattice](#), [ggplot2](#), [vi](#) grid commands, e.g., `grid.polygon()` rather than `polygons` vignettes.

The graphics packages in R can be organized roughly into

- Plotting**: Enhancements for specialized plots can be implemented in `alipack`, which also has a nice implementation of `rgl`. The package `ionion` for visualizing quaternions.
- Graphical Applications**: This is not much different subject area, like `grid`, `grid.layout`, `grid.colour`, etc.
- Effect ordering**: The `grid` package focuses on criteria. For ordering an array of displays, `grid`.
- Large Data Sets**: Large data sets are presented very quickly, and `hexbin` can bin bivariate data with `lattice`. An alternative is to use `seamons`.

- Trees and Graphs**: `ape` and `ade4` have function placement, so may be not useful for very large `igraph` have functions for plotting and layout.

- Graphics Systems**: `lattice` is built on top of the grid implementation of the system described in "A Grammatical approach to document layout".

- Devices**: Whereas grid is built on top of the R graphical basic supplies devices for PostScript, PDF, JPEG and the Gimp Toolkit, similar to `pyGTK2`, `RSVDev` standard. Trust Microsoft, `grid` provides a device driver.

- Colors**: The package `colorspace` provides a set of utilities for coding categorical variables (`rainbow`).

- Interactive Graphics**: There are several efforts to implement the device as well as link with other views of the data. GGobi's edge set functionality. The RoSUDA repository graphics tools contain functions for alpha blending, versions of R graphics using the `cairoDevice` and `Qt`.

- Development**: For development of specialized graphical Java device in the RoSUDA packages, though Java

CRAN packages:

- `ade4`
- `animation`
- `ape`
- `alipack`

## Les Graphiques avec ggplot2 Aide mémoire

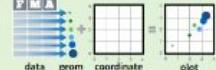

### Les Bases

ggplot2 est basé sur "grammar of graphics", le principe est que vous pouvez construire tous les graphiques à partir d'un même petit nombre d'éléments : un jeu de données, un ensemble de géoms (répères visuels) qui représentent les points de données et un système de coordonnées.

Pour afficher les valeurs de données, il faut utiliser les variables du jeu de données en tant que propriétés esthétiques du geom dans size, color, x et y.

Les graphiques se construisent avec `ggplot()` ou `qplot()` :

propriétés esthétiques      données      geom

`qplot(x = cyl, y = hwy, color = cyl, data = mpg, geom = "point")`

génère un graphique complet à partir des données, du geom et des propriétés esthétiques passées en paramètres et intègre de nombreux paramètres par défaut très utiles.

`ggplot(data = mpg, aes(x = cyl, y = hwy))`

initialise un graphique à compléter en ajoutant des calques. Il n'y a pas de calques par défaut, mais cela permet plus de contrôle que `qplot()`.

données      ajout de calques avec      calque = geom +

`ggplot(mpg, aes(hwy, cyl)) +  
 geom_point(aes(color = cyl)) +`

`geom_text(aes(label = cyl)) +`

`geom_bar(aes(x = cyl)) +`

`geom_boxplot(aes(x = cyl)) +`

`geom_hex(aes(x = cyl, y = hwy)) +`

`geom_jitter(aes(x = cyl, y = hwy)) +`

`geom_linerer(aes(x = cyl, y = hwy)) +`

`geom_map(aes(x = long, y = lat)) +`

`geom_rect(aes(x0 = long, y0 = lat, x1 = long + 1, y1 = lat + 1)) +`

```

- ❑ ggplot quickly adopted by analyst
- ❑ ggbio uses ggplot to offer genomic specificities
- ❑ Adapted to read NGS data (BAM/GFF/VCF) in object as GRanges, GAlignments etc.
- ❑ The generic function autoplot() works often very well
- ❑ Combine several tracks of the same regions (reads, coverage, transcripts) using the tracks() function from rtracklayer package
